

WILLIAM & MARY

CSCI 454/554 Computer and Network Security

Topic 5.2 Public Key Cryptography

WILLIAM & MARY

Outline

1. Introduction
2. RSA
3. Diffie-Hellman Key Exchange
4. Digital Signature Standard

2

WILLIAM & MARY

Introduction

WILLIAM & MARY

Public Key Cryptography

- Invented and published in 1975
- A *public / private key pair* is used
 - public key can be announced to everyone
 - private key is kept secret by the owner of the key
- Also known as *asymmetric* cryptography
- Much *slower* to compute than *secret key cryptography*

4

WILLIAM & MARY

Applications of Public Key Crypto

1. Message integrity with *digital signatures*
 Alice computes hash, signs with her private key (no one else can do this without her key)
 Bob verifies hash on receipt using Alice's public key using the verification equation

5

WILLIAM & MARY

Applications (Cont'd)

- The digital signature is verifiable by anybody
- Only one person can sign the message: *non-repudiation*
 - Non-repudiation is only achievable with public key cryptography

6

Applications (Cont'd)

WILLIAM & MARY

2. **Communicating securely** over an insecure channel
 - Alice encrypts plaintext using Bob's public key, and Bob decrypts ciphertext using his private key
 - No one else can decrypt the message (because they don't have Bob's private key)

7

Applications (Cont'd)

WILLIAM & MARY

3. **Secure storage** on insecure medium
 - Alice encrypts data using her public key
 - Alice can decrypt later using her private key
4. **User Authentication**
 - Bob proves his identity to Alice by using his private key to perform an operation (without divulging his private key)
 - Alice verifies result using Bob's public key

8

Applications (Cont'd)

WILLIAM & MARY

5. **Key exchange** for **secret key** crypto
 - Alice and Bob use public key crypto to negotiate a shared secret key between them

9

Public Key Algorithms

WILLIAM & MARY

- Public key algorithms covered in this class, and their applications

System	Encryption / Decryption?	Digital Signatures?	Key Exchange?
RSA	Yes	Yes	Yes
Diffie- Hellman			Yes
DSA		Yes	

10

Public-Key Requirements

WILLIAM & MARY

- It must be **computationally**
 - **easy** to generate a public / private key pair
 - **hard** to determine the private key, given the public key
- It must be **computationally**
 - **easy** to encrypt using the public key
 - **easy** to decrypt using the private key
 - **hard** to recover the plaintext message from just the ciphertext and the public key

11

Trapdoor One-Way Functions

WILLIAM & MARY

- **Trapdoor** one-way function
 - $Y = f_k(X)$: easy to compute if k and X are known
 - $X = f_k^{-1}(Y)$: easy to compute if k and Y are known
 - $X = f_k^{-1}(Y)$: hard if Y is known but k is **unknown**
- Goal of designing public-key algorithm is to find appropriate trapdoor one-way function

12

WILLIAM & MARY

The RSA Cipher

- WILLIAM & MARY
- ## RSA (Rivest, Shamir, Adleman)
- The most popular public key method
 - provides both public key encryption and digital signatures
 - Basis: **factorization of large numbers** is hard
 - Variable key length (**1024 bits** or greater)
 - Variable plaintext block size
 - plaintext** block size must be **smaller** than key size
 - ciphertext** block size is **same** as key size
- 14

- WILLIAM & MARY
- ## Generating a Public/Private Key Pair
- Find (using Miller-Rabin) large primes p and q
 - Let $n = p * q$
 - do not disclose p and q !
 - $\phi(n) = ???$
 - Choose an e that is **relatively prime to $\phi(n)$**
 - public** key = $\langle e, n \rangle$
 - Find $d =$ **multiplicative inverse of $e \bmod \phi(n)$** (i.e., $e * d = 1 \bmod \phi(n)$)
 - private** key = $\langle d, n \rangle$
- 15

- WILLIAM & MARY
- ## RSA Operations
- For plaintext message m and ciphertext c

Encryption: $c = m^e \bmod n, m < n$

Decryption: $m = c^d \bmod n$

Signing: $s = m^d \bmod n, m < n$

Verification: $m = s^e \bmod n$
- 16

- WILLIAM & MARY
- ## RSA Example: Encryption and Signing
- Choose $p = 23, q = 11$ (both primes)
 - $n = p * q = 253$
 - $\phi(n) = (p-1)(q-1) = 220$
 - Choose $e = 39$ (relatively prime to 220)
 - public** key = $\langle 39, 253 \rangle$
 - Find $e^{-1} \bmod 220 = d = 79$ (note: $39 * 79 \equiv 1 \bmod 220$)
 - private** key = $\langle 79, 253 \rangle$
- 17

- WILLIAM & MARY
- ## Example (Cont'd)
- Suppose plaintext $m = 80$

Encryption
 $c = 80^{39} \bmod 253 = \underline{\hspace{2cm}}$ ($c = m^e \bmod n$)

Decryption
 $m = \underline{\hspace{2cm}}^{79} \bmod 253 = 80$ ($c^d \bmod n$)

Signing (in this case, for entire message m)
 $s = 80^{79} \bmod 253 = \underline{\hspace{2cm}}$ ($s = m^d \bmod n$)

Verification
 $m = \underline{\hspace{2cm}}^{39} \bmod 253 = 80$ ($s^e \bmod n$)
- 18

Example (Cont'd)

- Suppose plaintext $m = 80$

Encryption
 $c = 80^{39} \bmod 253 = 37 \quad (c = m^e \bmod n)$

Decryption
 $m = 37^{79} \bmod 253 = 80 \quad (c^d \bmod n)$

Signing (in this case, for entire message m)
 $s = 80^{79} \bmod 253 = 224 \quad (s = m^d \bmod n)$

Verification
 $m = 224^{39} \bmod 253 = 80 \quad (s^e \bmod n)$

19

Using RSA for Key Negotiation

- Procedure
 - A sends random number $R1$ to B, encrypted with B's public key
 - B sends random number $R2$ to A, encrypted with A's public key
 - A and B both decrypt received messages using their respective private keys
 - A and B both compute $K = H(R1 \oplus R2)$, and use that as the shared key

20

Key Negotiation Example

- For Alice, $e = 39, d = 79, n = 253$
- For Bob, $e = 23, d = 47, n = 589 (=19*31)$
- Let $R1 = 15, R2 = 55$
 - Alice sends $306 = 15^{23} \bmod 589$ to Bob
 - Bob sends $187 = 55^{39} \bmod 253$ to Alice
 - Alice computes $R2 = 55 = 187^{79} \bmod 253$
 - Bob computes $R1 = 15 = 306^{47} \bmod 589$
 - A and B both compute $K = H(R1 \oplus R2)$, and use that as the shared key

21

Proof of Correctness ($D(E(m)) = m$)

- Given
 - public key = $\langle e, n \rangle$ and private key = $\langle d, n \rangle$
 - $n = p * q, \phi(n) = (p-1)(q-1)$
 - $e * d \equiv 1 \pmod{\phi(n)}$
- If encryption is $c = m^e \bmod n$, decryption...
 - $c^d \bmod n$
 - $= (m^e)^d \bmod n = m^{ed} \bmod n = m^{ed \bmod \phi(n)} \bmod n$
 - $= m \bmod n$ (why?)
 - $= m$ (since $m < n$)
- (digital signature proof is similar)

22

Is RSA Secure?

- $\langle e, n \rangle$ is public information
- If you could factor n into $p * q$, then
 - could compute $\phi(n) = (p-1)(q-1)$
 - could compute $d = e^{-1} \bmod \phi(n)$
 - would know the private key $\langle d, n \rangle$!
- But: factoring large integers is hard!
 - classical problem worked on for centuries; no known reliable, fast method

23

Security (Cont'd)

- At present, key sizes of 1024 bits are considered to be secure, but 2048 bits is better
- Tips for making n difficult to factor
 - p and q lengths should be similar (ex.: ~500 bits each if key is 1024 bits)
 - both $(p-1)$ and $(q-1)$ should contain a "large" prime factor
 - $\gcd(p-1, q-1)$ should be "small"
 - d should be larger than $n^{1/4}$

24

Attacks Against RSA

WILLIAM & MARY

- Brute force: try all possible private keys
 - can be defeated by using a large enough key space (e.g., 1024 bit keys or larger)
- Mathematical attacks
 1. factor n (possible for special cases of n)
 2. determine d directly from e , without computing $\phi(n)$
 - at least as difficult as factoring n

25

Attacks (Cont'd)

WILLIAM & MARY

- **Probable-message attack** (using $\langle e, n \rangle$)
 - encrypt **all possible** plaintext messages
 - try to find a match between the ciphertext and one of the encrypted messages
 - only works for small plaintext message sizes
 - Solution: pad plaintext message with random text before encryption
 - PKCS #1 v1 specifies this padding format:

00	02	R1	R2	R3	R4	R5	R6	R7	R8	00	data...
----	----	----	----	----	----	----	----	----	----	----	---------

each 8 bits long

26

Timing Attacks Against RSA

WILLIAM & MARY

- Recovers the private key from the **running time** of the decryption algorithm
- Computing $m = c^d \bmod n$ using repeated squaring algorithm:

```

• m = 1;
• for i = k-1 downto 1
  m = m*m mod n;
  if di == 1
    then m = m*c mod n;
• return m;

```

27

Timing Attacks (Cont'd)

WILLIAM & MARY

- The attack proceeds bit by bit
- Attacker assumed to know c, m
- Attacker is able to determine bit i of d because for some c and m , the highlighted step is extremely slow if $d_i = 1$

28

Countermeasures to Timing Attacks

WILLIAM & MARY

1. Delay the result if the computation is too fast
 - disadvantage: ?
2. Add a random delay
 - disadvantage?
3. **Blinding**: multiply the ciphertext by a random number before performing decryption

29

RSA's Blinding Algorithm

WILLIAM & MARY

- To confound timing attacks during decryption
 1. generate a random number r between 0 and $n-1$ such that $\gcd(r, n) = 1$
 2. compute $c' = c * r^e \bmod n$
 3. compute $m' = (c')^d \bmod n$ this is where timing attack would occur
 4. compute $m = m' * r^{-1} \bmod n$
- Attacker will not know what the bits of c' are
- Performance penalty: < 10% slowdown in decryption speed

30

File Encryption and Authentication

- Alice sends a large file to Bob without disclosing the content of the file to anybody else.
- Also make sure no other people can modify the message without being noticed.
- Conditions:
 - No secret key shared between Alice and Bob.
 - Alice and Bob know each other's RSA public key. (SK_A, PK_A) and (SK_B, PK_B)

31

Sender

$$M = E_{K_S}(F) \parallel E_{PK_B}(K_S) \parallel \text{Sig}_{SK_A}(E_{K_S}(F) \parallel E_{PK_B}(K_S))$$

32

Receiver

33

Diffie-Hellman Key Exchange

Diffie-Hellman Protocol

- For negotiating a shared secret key using only public communication
- Does **not** provide authentication of communicating parties
- What's involved?
 - p is a large prime number (about 512 bits)
 - g is a **primitive root** of p , and $g < p$
 - p and g are **publicly known**

35

D-H Key Exchange Protocol

Alice	Bob
Publishes or sends g and p	Reads g and p
Picks random number S_A <i>(and keeps private)</i>	Picks random number S_B <i>(and keeps private)</i>
Computes public key $T_A = g^{S_A} \text{ mod } p$	Computes public key $T_B = g^{S_B} \text{ mod } p$
Sends T_A to Bob, reads T_B from Bob	Sends T_B to Alice, reads T_A from Alice
Computes $T_B^{S_A} \text{ mod } p$	Computes $T_A^{S_B} \text{ mod } p$

=

36

Key Exchange (Cont'd) WILLIAM & MARY

- Alice and Bob have now both computed **the same secret** $g^{S_A S_B} \bmod p$, which can then be used as the **shared secret key K**
- S_A is the discrete logarithm of $g^{S_A} \bmod p$ and S_B is the discrete logarithm of $g^{S_B} \bmod p$

37

D-H Example WILLIAM & MARY

- Let $p = 353, g = 3$
- Let random numbers be $S_A = 97, S_B = 233$
- Alice computes $T_A = __ \bmod __ = 40 = g^{S_A} \bmod p$
- Bob computes $T_B = __ \bmod __ = 248 = g^{S_B} \bmod p$
- They exchange T_A and T_B
- Alice computes $K = __ \bmod __ = \mathbf{160} = T_B^{S_A} \bmod p$
- Bob computes $K = __ \bmod __ = \mathbf{160} = T_A^{S_B} \bmod p$

38

D-H Example WILLIAM & MARY

- Let $p = 353, g = 3$
- Let random numbers be $S_A = 97, S_B = 233$
- Alice computes $T_A = 3^{97} \bmod 353 = 40 = g^{S_A} \bmod p$
- Bob computes $T_B = 3^{233} \bmod 353 = 248 = g^{S_B} \bmod p$
- They exchange T_A and T_B
- Alice computes $K = 248^{97} \bmod 353 = \mathbf{160} = T_B^{S_A} \bmod p$
- Bob computes $K = 40^{233} \bmod 353 = \mathbf{160} = T_A^{S_B} \bmod p$

39

Why is This Secure? WILLIAM & MARY

- Discrete log problem:
 - given $T_A (= g^{S_A} \bmod p), g,$ and $p,$ it is **computationally infeasible** to compute S_A
 - (note: as always, to the best of our knowledge; doesn't mean there isn't a method out there waiting to be found)
 - same statement can be made for $T_B, g, p,$ and S_B

40

D-H Limitations WILLIAM & MARY

- Expensive exponential operation is required
 - possible timing attacks??
- Algorithm is useful for **key negotiation only**
 - i.e., not for public key encryption
- **Not** for user authentication
 - In fact, you can negotiate a key with a complete stranger!

41

Man-In-The-Middle Attack WILLIAM & MARY

- Trudy impersonates as Alice to Bob, and also impersonates as Bob to Alice

42

 MITM Attack (Cont'd) 

- Now, Alice thinks K1 is the shared key, and Bob thinks K2 is the shared key
- Trudy intercepts messages from Alice to Bob, and
 - decrypts (using K1), substitutes her own message, and encrypts for Bob (using K2)
 - likewise, intercepts and substitutes messages from Bob to Alice
- Solution???

43

 Authenticating D-H Messages 

- That is, you know who you're negotiating with, and that the messages haven't been modified
- Requires that communicating parties **already** share some kind of a secret
- Then use encryption, or a MAC (based on this previously-shared secret), of the D-H messages

44

 Using D-H in "Phone Book" Mode 

- Alice and Bob each choose a **semi-permanent** secret number, generate T_A and T_B
- Alice and Bob **publish** T_A, T_B , i.e., Alice can get Bob's T_B at any time, Bob can get Alice's T_A at any time
- Alice and Bob can then generate a semi-permanent shared key without communicating
 - but, they must be using the **same p and g**
- Essential requirement: **reliability** of the published values (no one can substitute false values)
 - how accomplished???

45

 Encryption Using D-H? 

- How to do key distribution + message encryption **in one step**
- Everyone computes and **publishes** their own individual $\langle p_i, g_i, T_i \rangle$, where $T_i = g_i^{S_i} \text{ mod } p_i$
- For Alice to communicate with Bob...
 - Alice picks a random secret S_A
 - Alice computes $g_B^{S_A} \text{ mod } p_B$
 - Alice uses $K_{AB} = T_B^{S_A} \text{ mod } p_B$ to encrypt the message
 - Alice sends encrypted message **along with** (unencrypted) $g_B^{S_A} \text{ mod } p_B$

46

 Encryption (Cont'd) 

- For Bob to decipher the encrypted message from Alice
 - Bob computes $K_{AB} = (g_B^{S_A})^{S_B} \text{ mod } p_B$
 - Bob decrypts message using K_{AB}

47

 Example 

- Bob publishes $\langle p_B, g_B, T_B \rangle = \langle 401, 5, 51 \rangle$ and keeps secret $S_B = 58$
- Steps
 - Alice picks a random secret $S_A = 17$
 - Alice computes $g_B^{S_A} \text{ mod } p_B = \text{___} \text{ mod } \text{___} = 173$
 - Alice uses $K_{AB} = T_B^{S_A} \text{ mod } p_B = \text{___} \text{ mod } \text{___} = 360$ to encrypt message M
 - Alice sends encrypted message along with (unencrypted) $g_B^{S_A} \text{ mod } p_B = 173$
 - Bob computes $K_{AB} = (g_B^{S_A})^{S_B} \text{ mod } p_B = \text{___} \text{ mod } \text{___} = 360$
 - Bob decrypts message M using K_{AB}

48

Example

- Bob publishes $\langle p_B, g_B, T_B \rangle = \langle 401, 5, 51 \rangle$ and keeps secret $S_B = 58$
- Steps
 - Alice picks a random secret $S_A = 17$
 - Alice computes $g_B^{S_A} \bmod p_B = 5^{17} \bmod 401 = 173$
 - Alice uses $K_{AB} = T_B^{S_A} \bmod p_B = 51^{17} \bmod 401 = \mathbf{360}$ to encrypt message M
 - Alice sends encrypted message along with (unencrypted) $g_B^{S_A} \bmod p_B = 173$
 - Bob computes $K_{AB} = (g_B^{S_A})^{S_B} \bmod p_B = 173^{58} \bmod 401 = \mathbf{360}$
 - Bob decrypts message M using K_{AB}

49

Picking g and p

- Advisable to change g and p periodically
 - the longer they are used, the more info available to an attacker
- Advisable **not** to use **same** g and p for everybody
- For "obscure mathematical reasons"...
 - $(p-1)/2$ should be prime
 - $g^{(p-1)/2} \equiv -1 \pmod p$

50

Digital Signature Standard (DSS)

51

Digital Signature Standard (DSS)

- Useful only for digital signing (**no** encryption or key exchange)
- Components
 - SHA-1** to generate a hash value (some other hash functions also allowed now)
 - Digital Signature Algorithm (DSA)** to generate the digital signature from this hash value
- Designed to be **fast** for the **signer** rather than verifier
 - e.g., for use in *smart cards*

52

Digital Signature Algorithm (DSA)

- Announce public parameters used for signing
 - pick p (a prime with ≥ 1024 bits) ex.: $p = 103$
 - pick q (a 160 bit prime) such that $q|(p-1)$
 - ex.: $q = 17$ (divides 102)
 - choose $g \equiv h^{(p-1)/q} \pmod p$, where $1 < h < (p-1)$, such that $g > 1$
 - ex.: if $h = 2, g = 2^6 \bmod 103 = 64$
 - note: g is of **order $q \bmod p$**

ex.: powers of 64 mod 103 =

64 79 9 61 93 81 34 13 8 100 14 72 76 23 30 66 1

17 values

53

DSA (Cont'd)

- User Alice generates a long-term private key x_M
 - random integer with $0 < x_M < q$ ex.: $x_M = 13$
- Alice generates a long-term public key y_M
 - $y_M = g^{x_M} \bmod p$ ex.: $y_M = 64^{13} \bmod 103 = 76$

54

DSA (Cont'd) WILLIAM & MARY

ex.: $p = 103, q = 17, g = 64, x_M = 13, y_M = 76$

- Alice randomly picks a private key k such that $0 < k < q$, and generates $k^{-1} \bmod q$

ex.: $k = 12, 12^{-1} \bmod 17 = 10$
- Signing message M

ex.: $H(M) = 75$

 - public key $r = (g^k \bmod p) \bmod q$

ex.: $r = (64^{12} \bmod 103) \bmod 17 = 4$
 - signature $s = [k^{-1}(H(M) + x_M r)] \bmod q$

ex.: $s = [10 * (75 + 13 * 4)] \bmod 17 = 12$
 - transmitted info = M, r, s

ex.: $M, 4, 12$

55

Verifying a DSA Signature WILLIAM & MARY

ex.: $p = 103, q = 17, g = 64, y_M = 76, H(M) = 75$

- Known : g, p, q, y_M
- Received from signer: M, r, s

ex.: $M, 4, 12$

- $w = (s)^{-1} \bmod q$

ex.: $w = 12^{-1} \bmod 17 = 10$
- $u_1 = [H(M)w] \bmod q$

ex.: $u_1 = 75 * 10 \bmod 17 = 2$
- $u_2 = (r * w) \bmod q$

ex.: $u_2 = 4 * 10 \bmod 17 = 6$
- $v = [(g^{u_1} * y_M^{u_2}) \bmod p] \bmod q$

ex.: $v = [(64^2 * 76^6) \bmod 103] \bmod 17 = 4$
- If $v = r$, then the signature is verified

56

Verifying DSA Signature WILLIAM & MARY

- Received: $M, r = 13, s = 24$

- $w = (s)^{-1} \bmod q = 24$
- $u_1 = [H(M)w] \bmod q = 22 * 24 \bmod 25 = 3$
- $u_2 = (r)w \bmod q = 13 * 24 \bmod 25 = 12$
- $v = [(g^{u_1} y_A^{u_2}) \bmod p] \bmod q = [5^3 * 56^{12} \bmod 101] \bmod 25 = 13$
- If $v = r$, then the signature is verified

57

Why Does it Work? WILLIAM & MARY

- Correct? The signer computes
 - $s = k^{-1} * (H(m) + x * r) \bmod q$
 - so $k = H(m) * s^{-1} + x * r * s^{-1}$
 - $= H(m) * w + x * r * w \bmod q$
- Since g has order q :
 - $g^k = g^{H(m)w} * g^{xrw}$
 - $= g^{H(m)w} * y^{rw}$
 - $= g^{u_1} * y^{u_2} \bmod p$, and
- $r = (g^k \bmod p) \bmod q = (g^{u_1} * y^{u_2} \bmod p) \bmod q = v$

58

Is it Secure? WILLIAM & MARY

- Given y_M , it is difficult to compute x_M
 - x_M is the discrete log of y_M to the base $g, \bmod p$
- Likewise, given r , it is difficult to compute k
- Cannot forge a signature without x_M
- Signatures are not repeated (only used once per message) and cannot be replayed

59

Assessment of DSA WILLIAM & MARY

- Slower to verify than RSA, but faster signing than RSA
- Key lengths of 2048 bits and greater are also allowed

60
