**CSCI 454/554 Computer and Network Security**

Topic 8.4 Firewalls and Intrusion Detection Systems (IDS)

---

---

---

---

---

---

---

---

 **Outline** WILLIAM & MARY

---

- Firewalls
  - Filtering firewalls
  - Proxy firewalls
- Intrusion Detection System (IDS)
  - Rule-based IDS
  - Anomaly detection IDS
  - Host-based vs. network-based IDS

2

---

---

---

---

---

---

---

---

 WILLIAM & MARY

---

**Overview of Firewalls**

3

---

---

---

---

---

---

---

---

 **Internet Security Mechanisms** WILLIAM & MARY

The diagram illustrates three stages of internet security using a brick wall metaphor. In the first stage, labeled 'Prevent: Firewall, IPsec, SSL', a thick brick wall blocks several incoming arrows (yellow, brown, red, black). In the second stage, labeled 'Detect: Intrusion Detection', a thinner brick wall has one arrow (red) passing through, with a small hole visible. In the third stage, labeled 'Survive/Response: Recovery, Forensics', the wall is very thin and the red arrow has passed through, leaving a large hole.

- Goal: prevent if possible; detect quickly otherwise; and confine the damage

4

---

---

---

---

---

---

---

---

 **Basic Terms** WILLIAM & MARY

- *Vulnerabilities*
- *Intrusions* (attacks) and Intrusion Detection Systems (IDS)
- *Alert or alarm*: message generated by IDS

5

---

---

---

---

---

---

---

---

 **Example Attacks** WILLIAM & MARY

- Disclosure, modification, and destruction of data
- Compromise host and then attack other systems
- Monitoring and capture of user passwords, then masquerade as authorized user
- Phishing attacks

6

---

---

---

---

---

---

---

---

**Firewalls** WILLIAM & MARY

- Provides secure connectivity between networks
- Implements and enforces a security policy for communication between networks

7

---

---

---

---

---

---

---

---

**Firewalls (Cont'd)** WILLIAM & MARY

- Many organizations have distinct needs
  - access by anyone to public data concerning the company
  - access only by employees to internal data
- Solution: inner and outer (DMZ) networks

8

---

---

---

---

---

---

---

---

**Firewall Capabilities** WILLIAM & MARY

- Controlled access
  - restrict incoming and outgoing traffic according to security policy
- Other functions
  - log traffic, for later analysis
  - network address translation
  - encryption / decryption
  - application (payload) transformations

9

---

---

---

---

---

---

---

---

 **Limitations of Firewalls** WILLIAM & MARY

- Cannot protect against traffic that does not cross it
  - i.e., there may be other ingress points to the network, such as modems or wireless access points, that bypass the firewall
  - doesn't protect against "inside" attacks
- Configuration of firewalls to accomplish a desired high-level security policy is non-trivial

10

---

---

---

---

---

---

---

---

 **Filtering and Proxy Firewalls** WILLIAM & MARY

11

---

---

---

---

---

---

---

---

 **Filtering** WILLIAM & MARY

- Compare traffic to patterns, then process traffic according to rules if matched
- Two styles
  - packet filtering
  - session filtering

12

---

---

---

---

---

---

---

---

**Packet Filtering** WILLIAM & MARY

- Patterns specify values in the header of a single packet, e.g.,
  - source IP address and port number
  - destination IP address and port number
  - transport protocol type

**Router / Firewall**

13

---

---

---

---

---

---

---

---

**Packet Filtering (cont'd)** WILLIAM & MARY

- Decisions made on a per-packet basis
  - no **state** information (about previous packets) is maintained or used
- Assessment
  - easy to implement
  - but limited capabilities
- May be subject to **tiny-fragment** attack
  - first fragment has only a few bytes
  - rest of TCP header in a second fragment, not examined by firewall

14

---

---

---

---

---

---

---

---

**Session Filtering** WILLIAM & MARY

- Packet decisions are made in the context of a *connection* or *flow* of packets
- If packet is the start of a new connection...
  - check against rules for new connections
- If packet is part of an existing connection...
  - check against state-based rules for existing connections
  - update state of this connection

15

---

---

---

---

---

---

---

---

## Session Filtering (cont'd) WILLIAM & MARY

- Assessment
  - more powerful than packet filtering, can recognize more sophisticated threats or implement more complex policies
  - also more expensive to implement

**Router / Firewall**

16

---

---

---

---

---

---

---

---

## Application: Telnet WILLIAM & MARY

**Telnet Server**

port=23

**Telnet Client**

port=1234

- ❶ Client opens channel to server; tells server its port number. The ACK bit is not set when initiating the connection but will be set on the remaining packets.
- ❷ Server acknowledges.

17

---

---

---

---

---

---

---

---

## Example: Firewall Access for Telnet WILLIAM & MARY

**Format:**

```
access-list <rule number>
<permit|deny>
<protocol>
<SOURCE host with IP address|any|IP address and mask>
[<gt|eq port number>]
<DEST host with IP address|any|IP address and mask>
[<g|leq port number>]
```

**Note: any packets not explicitly permitted in an access list assumed to be denied or dropped.**

The following allows user to telnet from an IP address (172.168.10.11) to any destination, but not vice-versa:

```
access-list 100 permit tcp host 172.168.10.11 gt 1023 any eq 23
! Allows packets out to remote Telnet servers
access-list 101 permit tcp any eq 23 host 172.168.10.11 established
! Allows returning packets to come back in. It verifies that the ACK bit is set
```

```
interface Ethernet 0
access-list 100 out ! Apply the first rule to outbound traffic
access-list 101 in ! Apply the second rule to inbound traffic
```

18

---

---

---

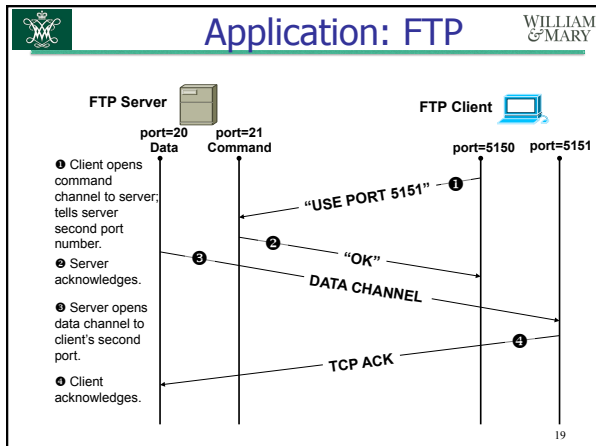

---

---

---

---

---

---

---

---

---

---

---

---

---

## Example: Firewall Access for FTP

Allow a user to FTP (not passive FTP) from any IP address to the FTP server (172.168.10.12) :

```

access-list 100 permit tcp any gt 1023 host 172.168.10.12 eq 21
access-list 100 permit tcp any gt 1023 host 172.168.10.12 eq 20
! Allows packets from any client to the FTP control and data ports
access-list 101 permit tcp host 172.168.10.12 eq 21 any gt 1023
access-list 101 permit tcp host 172.168.10.12 eq 20 any gt 1023
! Allows FTP server to send packets back to any IP address with TCP ports > 1023

interface Ethernet 0
access-list 100 in ! Apply the first rule to inbound traffic
access-list 101 out ! Apply the second rule to outbound traffic
    
```

20

---

---

---

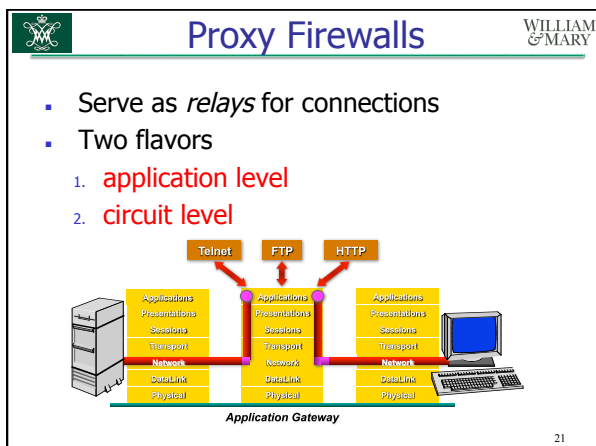

---

---

---

---

---

---

---

---

---

---

---

---

---

## Application Proxies

WILLIAM & MARY

- Understand specific application protocols, e.g., HTTP, SMTP, Telnet
  - proxy 'impersonates' both one side of connection to the other
- Can do arbitrary processing / inspection of application payloads
  - ex.: check mail for viruses before forwarding
- Computationally expensive
- Must write a new proxy application to support new protocols

22

---

---

---

---

---

---

---

---

## Application Proxies (Cont'd)

WILLIAM & MARY

- May require hosts inside the organization to be configured to use the proxy

23

---

---

---

---

---

---

---

---

## Circuit-Level Proxies

WILLIAM & MARY

- Sets up two connections, one to inside user, one to outside server
  - i.e., proxy at the TCP level, rather than the application level
  - client programs **must** be aware they are using a circuit-level proxy, by linking to modified libraries
- Users must authenticate to proxy before connection to outside will be established
- Example protocol: SOCKS

24

---

---

---

---

---

---

---

---

 WILLIAM & MARY

## Overview of IDS

25

---

---

---

---

---

---

---

---

 WILLIAM & MARY

## Attack Stages

- Cyber Kill Chain
  - Intelligence gathering: attacker probes the system to determine vulnerabilities
  - Planning: deciding what resource to attack and how
  - Attack execution
  - Hiding: covering traces of the attack
  - Preparation for future attacks: install "back doors" for unhindered access

26

---

---

---

---

---

---

---

---

 WILLIAM & MARY

## IDS

- Detect if attacks are being attempted, or if system has been compromised
- Desirable features
  - Accuracy
  - Fast
  - Flexible, general
  - Results easy to understand

27

---

---

---

---

---

---

---

---

 **Measuring Accuracy** WILLIAM & MARY

- Events are actions occurring in the system (file accesses, login attempts, etc.)
  - an *intrusion* (I) is an event that **is** part of an attack
  - an *alarm* (A) is generated if an event **is diagnosed** as being an intrusion

	Intrusion	Not an Intrusion
Alarm Generated	True positive	False positive
Alarm Not Generated	False negative	True negative

28

---

---

---

---

---

---

---

---

 **Measuring (Cont'd)** WILLIAM & MARY

- True positive rate (TPR): fraction of intrusions correctly diagnosed (detected)
- False negative rate: fraction of intrusions incorrectly diagnosed (not detected)
  - $FNR = 1 - TPR$
- True negative rate (TNR): fraction of non-intrusions correctly diagnosed
- False positive rate: fraction of non-intrusions incorrectly diagnosed
  - $FPR = 1 - TNR$

29

---

---

---

---

---

---

---

---

 **Which Ones Count** WILLIAM & MARY

- It's trivial to have 100% TPR, and trivial to have 0% FPR
  - how?
- Needed: both

30

---

---

---

---

---

---

---

---

**Example**

- 70,000 events, 300 intrusions, 2800 alarms (of which 298 are correct diagnoses, 2502 are incorrect)
- TPR:  $298 / 300 = 99.3\%$
- FNR: 0.7%
- TNR:  $(70000 - 300 - 2502) / (70000 - 300) = 96.4\%$
- FPR: 3.6%

31

---

---

---

---

---

---

---

---

**"Base-Rate Fallacy" Illustrated**

- IDS often suffers from **base-rate fallacy**
  - intrusions are rare events
  - non-intrusions are common
  - correctly detected intrusions are swamped by **incorrectly** detected non-intrusions!
- Previous example: only 298 out of 2800 alarms (**10.6%**) are correct
  - in reality, often less than 1% of alarms are real intrusions

32

---

---

---

---

---

---

---

---

**Components of IDS**

*Assumes: system activities are observable by sensors*

```

    graph TD
      AR[Audit Records] --> ADP[Audit Data Preprocessor]
      ADP --> AD[Activity Data]
      DM[(Detection Models)] --> DE[Detection Engine]
      DT[(Decision Table)] --> DE
      AD --> DE
      DE --> AL[Alarms]
      AL --> N[Notifier]
      N --> AR2[Action/Report]
      AR2 --> I[Icon of person and shield]
  
```

33

---

---

---

---

---

---

---

---

WILLIAM & MARY

## Signature-Based IDS

34

---

---

---

---

---

---

---

---

WILLIAM & MARY

## Basic IDS Techniques

1. **Misuse** detection
  - use attack *signatures* (characteristics of real attacks, e.g., illegal sequences of system calls, invalid packets, etc.)
  - can only detect already-known attacks
  - false positive rate is low, but false negative rate is high

35

---

---

---

---

---

---

---

---

WILLIAM & MARY

## Detection (Cont'd)

2. **Anomaly** detection
  - uses a model of "normal" system behavior
  - tries to detect **deviations** from this behavior, e.g., raises an alarm when a statistically rare event occurs
  - can potentially detect new (not previously-encountered) attacks
  - low false negative rate, high false positive rate
  - Which is better?

36

---

---

---

---

---

---

---

---

 **Ex.: Misuse vs. Anomaly Detection** WILLIAM & MARY

Password file modified	?
Four failed login attempts	?
Failed connection attempts on 50 sequentially-numbered ports	?
User who usually logs in around 10am from dorm logs in at 4:30am from an IP address in Lower Slobovia	?
UDP packet to port 1434 (Slammer Worm)	?

37

---

---

---

---

---

---

---

---

 **Example Signatures** WILLIAM & MARY

- A sequence of connection attempts to a large number of ports
- A privileged program spawning a shell
- A network packet that has lots of NOOP instruction bytes in it
- Program input containing a very long string (parameter value)
- A large number of TCP SYN packets sent, with no ACKs coming back

38

---

---

---

---

---

---

---

---

 **Signature Generation** WILLIAM & MARY

- Research challenge: fast, automatic extraction of signatures for **new attacks**
  - **honeypots** are useful for attracting attacks to generate signatures
- Attack signatures are usually very specific
  - automated engines now generate unlimited **variants** of a single attack
  - program obfuscation, self-decrypting code
- Possible response: find attack characteristics that are **difficult to conceal** / obfuscate

39

---

---

---

---

---

---

---

---

 WILLIAM & MARY

## Anomaly-Based IDS

40

---

---

---

---

---

---

---

---

 WILLIAM & MARY

## Anomaly Detection

- Collect a profile of “normal” behavior
  - called *training phase*
  - works best for small, well-defined, **stable** systems
- IDS compares operational system to this profile, and flags **deviations**

41

---

---

---

---

---

---

---

---

 WILLIAM & MARY

## Examples of Metrics

- **Count** of the number of occurrences of an event per unit time
  - if count exceeded, raise an alarm
- **Time** elapsed between events
  - if time too small, raise an alarm
- Resource **utilization**
  - if utilization too high, raise an alarm
- **Statistical measures**
  - mean, standard deviation, etc.

42

---

---

---

---

---

---

---

---

 **Examples (Cont'd)** WILLIAM & MARY

- Markov process: use expected likelihood of transition from one system state to another, or from one output to another
- Short **sequences** of events
  - ex. suppose the normal sequences of **system calls** during execution of two programs has been measured
  - any serious deviation from such sequences will be flagged as possible signs of an attack

43

---

---

---

---

---

---

---

---

 **Building Profiles** WILLIAM & MARY

- Profiles are **updated** regularly, and older data must be "aged" out
  - ex.:  $m_t = \alpha * \text{most recent measured value} + (1-\alpha)*m_{t-1}$
  - where  $m_t$  is expected value for time period  $t$ ,  $\alpha$  is an **experimentally-derived** weighting factor between .5 and 1.0
- Risk: **attacker trains IDS** to accept his activity as normal
  - i.e., training data should be free of intrusions, or intrusions must be properly classified in the training data!

44

---

---

---

---

---

---

---

---

 **Examples of Data Mining Techniques** WILLIAM & MARY

- **Association rule learning** (find interesting relations between variables)
- **Principal components analysis** (isolate and focus on the high variance variables)
- **Cluster analysis** (group data into categories based on similarities)
- ...

45

---

---

---

---

---

---

---

---

## Conventional View

WILLIAM & MARY

- Anomaly-based IDS by itself generates too many false positives
- **Combination** of anomaly-based and signature-based is **best**

46

---

---

---

---

---

---

---

---

WILLIAM & MARY

## Host-Based vs. Network-Based IDS

47

---

---

---

---

---

---

---

---

## Where Is the IDS Deployed?

WILLIAM & MARY

- **Host-based** intrusion detection system (HIDS)
  - monitor activity on a single host
- **Network-based** intrusion detection (NIDS)
  - monitor traffic, examine packet headers and payloads

48

---

---

---

---

---

---

---

---

 **Host-Based IDS** 

- Use OS auditing and monitoring mechanisms to find applications taken over by an attacker. Ex.:
  - log all system events (e.g., file accesses)
  - monitor shell commands and system calls executed
- Advantage: better visibility into behavior of individual applications running on the host
- Example application: detecting **rootkits**

49

---

---

---

---

---

---

---

---

 **Host-Based (Cont'd)** 

- **Drawbacks** / limitations
  - need an IDS for every machine
  - if attacker takes over machine, can tamper with IDS binaries and modify audit logs
  - only local view of the attack

50

---

---

---

---

---

---

---

---

 **Rootkit** 

- **Rootkit** is a set of "Trojan" system binaries
- Break into a host, download rootkit by FTP, unpack, compile and install
- Possibly turn off anti-virus / IDS
- Hides its own presence!
  - installs hacked binaries for common system monitoring commands, e.g., **netstat**, **ps**, **ls**, **du**, **login**
- "Sniff" user passwords

51

---

---

---

---

---

---

---

---

 **File Integrity Checking** WILLIAM & MARY

- Tripwire
  - Records **hashes** of critical files and binaries
  - System periodically checks that files have not been modified by re-computing and comparing hash
- Ways to bypass?

52

---

---

---

---

---

---

---

---

 **Network-Based IDS** WILLIAM & MARY

- Inspects network traffic
  - passive (unlike packet-filtering firewalls)
  - often handled by a router or firewall
- Monitors user activities
  - e.g., protocol violations, unusual connection patterns, attack strings in packet payloads
- Advantage: single NIDS can protect many hosts and look for widespread patterns of activity

53

---

---

---

---

---

---

---

---

 **Network-Based ... (cont'd)** WILLIAM & MARY

- Drawbacks / limitations
  - may be easily defeated by **encryption** (data portions and some header information can be encrypted)
  - not all attacks arrive from the network
  - must monitor, record and process **huge amount of traffic** on high-speed links
- Attack: overload NIDS with huge data streams, then attempt the intrusion

54

---

---

---

---

---

---

---

---

 **Popular NIDS : Snort** WILLIAM & MARY

- Popular open-source tool
- Large (> 4000) ruleset for vulnerabilities;  
Ex.:

“Date: 2005-04-05  
Synopsis: the Sourcefire Vulnerability Research Team (VRT) has learned of serious vulnerabilities affecting various implementations of Telnet [...] Programming errors in the telnet client code from various vendors may present an attacker with the opportunity to overflow a fixed length buffer [...] Rules to detect attacks against this vulnerability are included in this rule pack”

55

---

---

---

---

---

---

---

---

 **Some Snort Rule Categories** WILLIAM & MARY

- Backdoors    Multimedia    POP    Telnet
- Chat        MySQL        RPC    TFTP
- DDoS        NETBIOS     Scan    Virus
- Finger      NNTP        Shellcode    Web...
- FTP         Oracle       SMTP    X11
- ICMP        P2P         SNMP
- IMAP                    SQL

56

---

---

---

---

---

---

---

---

 **Snort Rule Syntax** WILLIAM & MARY

- Each snort rule has two logical sections: **rule header** and **rule options**
  - **rule header** contains action, protocol, source (IP address/port), direction, destination (IP address/port)
  - **rule option** contains alert messages, info on which parts of packet to be inspected

57

---

---

---

---

---

---

---

---

 **Snort Rule Examples** WILLIAM & MARY

- **alert icmp \$EXTERNAL\_NET any <> \$HOME\_NET any**  
 (msg:"DDOS Stacheldraht agent->handler (skillz)";  
 content:"skillz";  
 itype:0;  
 icmp\_id:6666; reference:url,staff.washington.edu/dittrich/misc/  
 stacheldraht.analysis;  
 classtype:attempted-dos;  
 sid:1855; rev:2;)
- **alert any any -> 192.168.1.0/24 any**  
 (flags:A; ack:0; msg: "NMAP TCP ping");  
 # nmap send TCP ACK pkt with ack field set to 0
- **alert tcp \$EXTERNAL\_NET any -> \$HTTP\_SERVERS**  
**\$HTTP\_PORTS**  
 (msg:"WEB-IIS cmd.exe access"; flow:to\_server,established;  
 content:"cmd.exe";  
 nocase;  
 classtype:web-application-attack;  
 sid:1002; rev:5;)

58

---

---

---

---

---

---

---

---

 **Detecting Attack Strings** WILLIAM & MARY

- Scanning for a signature in each packet is not enough
  - attacker can split attack string into several packets; will defeat **stateless** NIDS
- Recording just previous packet's text is not enough
  - attacker can send packets out of order
- Attacker can use TCP tricks so that certain packets are seen by NIDS but dropped by the receiving application

59

---

---

---

---

---

---

---

---

 **Honeypots** WILLIAM & MARY

- Decoy systems to lure attackers
  - away from accessing critical systems
  - to collect information of their activities
  - to encourage attacker to stay on system so administrator can respond
- Filled with fabricated information
- High-interaction decoy vs. Low-interaction decoy
- Instrumented to collect detailed information on attackers activities
- May be single or multiple networked systems

60

---

---

---

---

---

---

---

---

## Summary

WILLIAM  
& MARY

1. Firewalls widely used, packet filters most common
  - one valuable technique among many
2. IDS (both host-based and network-based) widely used
3. Attacks are constantly evolving; the "arms race"
4. False alarm volume, and providing clear feedback to administrators, is a problem

61

---

---

---

---

---

---

---

---
