# CSCI312 Principles of Programming Languages 

LL Parsing

Xu Liu

Derived from Keith Cooper's COMP 412 at Rice University

## Recap

## Syntactic Analysis

Phase also known as: parser
Purpose is to recognize source structure
Input: tokens
Output: parse tree or abstract syntax tree
A recursive descent parser is one in which each nonterminal in the grammar is converted to a function which recognizes input derivable from the nonterminal.

## Terms

Nullable non-terminals
First set

## $T(E B N F)=$ Code: $A \rightarrow W$

1 If $w$ is nonterminal, call it.
2 If $w$ is terminal, match it against given token.
3 If $w$ is $\left\{w^{\prime}\right\}$ :
while (token in First( $w^{\prime}$ )) $T\left(w^{\prime}\right)$
4 If w is: w 1 | ... | wn,
switch (token) \{ case First(wl): T(wl); break;
case First(wn): T(wn); break;

5 Switch (cont.): If some wi is empty, use: default: break;

Otherwise default: error(token);

6 If $w=\left[w^{\prime}\right]$, rewrite as $\left(\mid w^{\prime}\right)$ and use rule 4.
7 If $w=X 1 \ldots \mathrm{Xn}, \mathrm{T}(\mathrm{w})=$
T(X1); ... T(Xn);

## Outline

See more general problems in a top down parser Backtracking - select appropriate productions Left recursion - revise grammars
Predictive parsing - more than recursive descent Table-driven parsing

## Parsing Techniques

Top-down parsers (LL(1), recursive descent)

- Start at the root of the parse tree and grow toward leaves
- Pick a production \& try to match the input
- Bad "pick" $\Rightarrow$ may need to backtrack
- Some grammars are backtrack-free

Bottom-up parsers (LR(1), operator precedence)

- Start at the leaves and grow toward root
- As input is consumed, encode possibilities in an internal state
- Start in a state valid for legal first tokens
- Bottom-up parsers handle a large class of grammars

## Top-down Parsing

A top-down parser starts with the root of the parse tree
The root node is labeled with the goal symbol of the grammar
Top-down parsing algorithm:
Construct the root node of the parse tree
Repeat until lower fringe of the parse tree matches the input string
1 At a node labeled A, select a production with $A$ on its lhs and, for each symbol on its rhs, construct the appropriate child
2 When a terminal symbol is added to the fringe and it doesn't match the fringe, backtrack
3 Find the next node to be expanded
(label $\in N T$ )
The key is picking the right production in step 1

- That choice should be guided by the input string

## Remember the expression grammar?

We will call this version "the classic expression grammar"

- from last lecture

| 0 | Goal |  | Expr |  |
| :---: | :---: | :---: | :---: | :---: |
| 1 | Expr | $\rightarrow$ | Expr + Term |  |
| 2 |  | - | Expr - Term |  |
| 3 |  | 1 | Term |  |
| 4 | Term | $\rightarrow$ | Term * Factor | And the input $\underline{x}-\underline{2}^{*} \underline{y}$ |
| 5 |  | 1 | Term / Factor |  |
| 6 |  | 1 | Factor |  |
| 7 | Factor | $\rightarrow$ | ( Expr ) |  |
| 8 |  | 1 | number |  |
| 9 |  |  | id |  |

## Example

Let's try $\underline{x}-\underline{2}^{*} \underline{y}$ :

| Rule Sentential Form | Input |
| :---: | :--- |
| - Goal | $\uparrow \underline{x}-\underline{2}^{*} \underline{y}$ |

## Example

Let's try $\underline{x}-\underline{2}^{*} \underline{y}$ :

| Rule | Sentential Form | Input |
| :---: | :--- | :--- |
| - | Goal | $\uparrow \underline{x}-\underline{2}^{*} \underline{y}$ |
| 0 | Expr | $\uparrow \underline{x}-\underline{2}^{*} \underline{y}$ |
| 1 | Expr + Term | $\uparrow \underline{x}-\underline{2}^{*} \underline{y}$ |
| 3 | Term + Term | $\uparrow \underline{x}-\underline{2}^{*} \underline{y}$ |
| 6 | Factor + Term | $\uparrow \underline{x}-\underline{2}^{*} \underline{y}$ |
| 9 | $\langle i d, \underline{x}\rangle+$ Term | $\uparrow \underline{x}-\underline{2}^{*} \underline{y}$ |
| $\rightarrow$ | $\langle i d, x\rangle+$ Term | $\underline{x} \uparrow-\underline{2}^{*} \underline{y}$ |

This worked well, except that "-" doesn't match "+"
The parser must backtrack to here

Example
Continuing with $\underline{x}-\underline{2}^{*} \underline{y}$ :

$\Rightarrow$ Now, we need to expand Term - the last NT on the fringe

## Example

Trying to match the "2" in $\underline{x}-\underline{2}^{*} \underline{y}$ :

| Rule | Sentential Form | Indut |
| :---: | :--- | :--- |
| $\rightarrow$ | $\langle i d, \underline{x}\rangle-$ Term | $\underline{x}-\uparrow \underline{2}^{*} \underline{y}$ |
| 6 | $\langle i d, \underline{x}\rangle-$ Factor | $\underline{x}-\uparrow \underline{2}^{*} \underline{y}$ |
| 8 | $\langle i d, \underline{x}\rangle-\langle$ num, $\underline{2}\rangle$ | $\underline{x}-\uparrow \underline{2}^{*} \underline{y}$ |
| $\rightarrow$ | $\langle i d, x\rangle-\langle n u m, \underline{2}\rangle$ | $\underline{x}-\underline{2} \uparrow^{*} \underline{y}$ |

Where are we?

- "2" matches "2"

- We have more input, but no NTs left to expand
- The expansion terminated too soon
$\Rightarrow$ Need to backtrack

Example
Trying again with "2" in $\underline{x}-\underline{2}$ * $\underline{x}$ :

The Point:
The parser must make the right choice when it expands a NT. Wrong choices lead to wasted effort.

## Another possible parse

Other choices for expansion are possible

| Rule | Sentential Form | Input |
| :---: | :---: | :---: |
| - | Goal | $\uparrow \underline{x}-\underline{2} * \underline{y}$ |
| 0 | Expr | $\uparrow$ ¢- ${ }^{*}$ \% |
| 1 | Expr +Term | x-2* |
| 1 | Expr + Term + Term |  |
| 1 | Expr + Term + Term + Term | $\underline{x}-\underline{2} \times$ |
| 1 | And so on | $\underline{x}-2^{*} y$ |

This expansion doesn't terminate

- Wrong choice of expansion leads to non-termination
- Non-termination is a bad property for a parser to have
- Parser must make the right choice

## Left Recursion

Top-down parsers cannot handle left-recursive grammars
Formally,
A grammar is left recursive if $\exists A \in N T$ such that
$\exists$ a derivation $A \Rightarrow^{+} A \alpha$, for some string $\alpha \in(N T \cup T)^{+}$

Our classic expression grammar is left recursive

- This can lead to non-termination in a top-down parser
- In a top-down parser, any recursion must be right recursion
- We would like to convert the left recursion to right recursion

Non-termination is always a bad property in a compiler

## Eliminating Left Recursion

To remove left recursion, we can transform the grammar
Consider a grammar fragment of the form
Fee $\rightarrow$ Fee $\alpha$
| $\beta$
where neither $\alpha$ nor $\beta$ start with Fee

We can rewrite this fragment as

Fee $\rightarrow \beta$ Fie
Fie $\rightarrow \alpha$ Fie

where Fie is a new non-terminal

The new grammar defines the same language as the old grammar, using only right recursion.

## Eliminating Left Recursion

The expression grammar contains two cases of left recursion

| Expr | $\rightarrow$ Expr + Term | Term | $\rightarrow$ Term * Factor |
| ---: | :--- | ---: | :--- |
| $\mid$ Expr - Term |  | I Term * Factor |  |
| \| Term |  | I Factor |  |

Applying the transformation yields

| Expr | $\rightarrow$ Term Expr' | Term | $\rightarrow$ Factor Term |
| :--- | :--- | :--- | :--- |
| Expr | $\rightarrow+$ Term Expr' | Term | $\rightarrow$ * Factor Term |
|  | $\mid-$ Term Expr' |  | $\mid /$ Factor Term |
|  | $\mid \varepsilon$ |  | $\mid \varepsilon$ |

These fragments use only right recursion
Right recursion often means right associativity. In this case, the grammar does not display any particular associative bias.

## Picking the "Right" Production

If it picks the wrong production, a top-down parser may backtrack
Alternative is to look ahead in input \& use context to pick correctly
How much lookahead is needed?

- In general, an arbitrarily large amount

Fortunately,

- Large subclasses of CFGs can be parsed with limited lookahead
- Most programming language constructs fall in those subclasses

Among the interesting subclasses are $\operatorname{LL}(1)$ and $\operatorname{LR}(1)$ grammars

We will focus, for now, on LL(1) grammars \& predictive parsing

## Predictive Parsing

Basic idea
Given $A \rightarrow \alpha \mid \beta$, the parser should be able to choose between $\alpha \& \beta$
First sets
For some rhs $\alpha \in G$, define $\operatorname{FIRST}(\alpha)$ as the set of tokens that appear as the first symbol in some string that derives from $\alpha$ That is, $\underline{x} \in \operatorname{FIRST}(\alpha)$ iff $\alpha \Rightarrow^{*} \underline{x} \gamma$, for some $\gamma$

## Predictive Parsing

Basic idea
Given $A \rightarrow \alpha \mid \beta$, the parser should be able to choose between $\alpha \& \beta$
FIRST sets
For some rhs $\alpha \in G$, define $\operatorname{FIRST}(\alpha)$ as the set of tokens that appear as the first symbol in some string that derives from $\alpha$
That is, $\underline{x} \in \operatorname{FIRST}(\alpha)$ iff $\alpha{ }^{*} \underline{x} \gamma$, for some $\gamma$
The LL(1) Property
If $A \rightarrow \alpha$ and $A \rightarrow \beta$ both appear in the grammar, we would like

$$
\operatorname{FIRST}(\alpha) \cap \operatorname{FIRST}(\beta)=\varnothing
$$

This would allow the parser to make a correct choice with a lookahead of exactly one symbol!

## This is almost correct <br> See the next slide

## Predictive Parsing

What about $\varepsilon$-productions?
$\Rightarrow$ They complicate the definition of $\operatorname{LL}(1)$
If $A \rightarrow \alpha$ and $A \rightarrow \beta$ and $\varepsilon \in \operatorname{FIRST}(\alpha)$, then we need to ensure that FIRST( $\beta$ ) is disjoint from FOLLOW(A), too, where

Follow $(A)$ = the set of terminal symbols that can immediately follow $A$ in a sentential form

Define FIRST ${ }^{+}(A \rightarrow \alpha)$ as

- FIRst $(\alpha) \cup$ Follow $(A)$, if $\varepsilon \in \operatorname{FIRST}(\alpha)$
- First( $\alpha$ ), otherwise

Then, a grammar is $L L(1)$ iff $A \rightarrow \alpha$ and $A \rightarrow \beta$ implies

$$
\operatorname{FIRST}^{+}(A \rightarrow \alpha) \cap \operatorname{FIRST}^{+}(A \rightarrow \beta)=\varnothing
$$

## Recursive Descent Parsing

Recall the expression grammar, after transformation

| 0 | Goal | $\rightarrow$ | Expr |
| :--- | :--- | :--- | :--- |
| 1 | Expr | $\rightarrow$ | Term Expr' |
| 2 | Expr | $\rightarrow$ | + Term Expr' |
| 3 |  | $\mid$ | - Term Expr' |
| 4 |  | $\mid$ | $\varepsilon$ |
| 5 | Term | $\rightarrow$ | Factor Term' |
| 6 | Term' | $\rightarrow$ | * Factor Term |
| 7 |  | $\mid$ | $/$ Factor Term |
| 8 |  | $\mid$ | $\varepsilon$ |
| 9 | Factor | $\rightarrow$ | (Expr) |
| 10 |  | $\mid$ | number |
| 11 |  | $\mid$ | id |

This produces a parser with six mutually recursive routines:

- Goal
- Expr
- EPrime
- Term
- TPrime
- Factor

Each recognizes one NT or T
The term descent refers to the direction in which the parse tree is built.

## What If My Grammar Is Not LL(1)?

Can we transform a non-LL(1) grammar into an LL(1) grammar?

- In general, the answer is no
- In some cases, however, the answer is yes

Assume a grammar $G$ with productions $A \rightarrow \alpha \beta_{1}$ and $A \rightarrow \alpha \beta_{2}$

- If $\alpha$ derives anything other than $\varepsilon$, then

$$
\operatorname{FIRST}^{+}\left(A \rightarrow \alpha \beta_{1}\right) \cap \operatorname{FIRST}^{+}\left(A \rightarrow \alpha \beta_{2}\right) \neq \varnothing
$$

- And the grammar is not $\operatorname{LL}(1)$

If we pull the common prefix, $\alpha$, into a separate production, we may make the grammar LL(1).

$$
A \rightarrow \alpha A^{\prime}, A^{\prime} \rightarrow \beta_{1} \text { and } A^{\prime} \rightarrow \beta_{2}
$$

Now, if $\operatorname{FIRST}^{+}\left(A^{\prime} \rightarrow \beta_{1}\right) \cap \operatorname{FIRST}^{+}\left(A^{\prime} \rightarrow \beta_{2}\right)=\varnothing, G$ may be $L L(1)$

## What If My Grammar Is Not LL(1)?

Left Factoring
For each nonterminal A
find the longest prefix a common to 2 or more alternatives for $A$ if $\alpha \neq \varepsilon$ then
replace all of the productions

$$
\begin{aligned}
& A \rightarrow \alpha \beta_{1}\left|\alpha \beta_{2}\right| \alpha \beta_{3}|\ldots| \alpha \beta_{n} \mid \gamma \\
& \text { with } \\
& A \rightarrow \alpha A^{\prime} \mid \gamma \\
& A^{\prime} \rightarrow \beta_{1}\left|\beta_{2}\right| \beta_{3}|\ldots| \beta_{n}
\end{aligned}
$$

Repeat until no nonterminal has alternative rhs' with a common prefix
This transformation makes some grammars into LL(1) grammars There are languages for which no LL(1) grammar exists

## Left Factoring Example

Consider a simple right-recursive expression grammar

| 0 | Goal | $\rightarrow$ | Expr |
| :---: | :---: | :---: | :---: |
| 1 | Expr | $\rightarrow$ | Term + Expr |
| 2 |  | 1 | Term-Expr |
| 3 |  | 1 | Term |
| 4 | Term | $\rightarrow$ | Factor * Term |
| 5 |  | 1 | Factor / Term |
| 6 |  | 1 | Factor |
| 7 | Factor | $\rightarrow$ | number |
| 8 |  |  |  |

To choose between 1, 2, \& 3, an $L L(1)$ parser mus $\dagger$ look pas $\dagger$ the number or id to see the operator.

$$
\begin{gathered}
\operatorname{FIRST}^{+}(1)=\operatorname{FIRST}^{+}(2)=\operatorname{FIRST}^{+}(3) \\
\text { and } \\
\operatorname{FIRST}^{+}(4)=\operatorname{FIRST}^{+}(5)=\operatorname{FIRST}^{+}(6) \\
\text { Let's left factor this grammar. }
\end{gathered}
$$

## Left Factoring Example

After Left Factoring, we have

| 0 | Goal | $\rightarrow$ | Expr |
| :---: | :--- | :--- | :--- |
| 1 | Expr | $\rightarrow$ | Term Expr' |
| 2 | Expr' | $\rightarrow$ | + Expr |
| 3 |  | $\mid$ | - Expr |
| 4 |  | $\mid$ | $\varepsilon$ |
| 5 | Term | $\rightarrow$ | Factor Term' |
| 6 | Term' | $\rightarrow$ | *erm |
| 7 |  | $\mid$ | $/$ Term |
| 8 |  | $\mid$ | $\varepsilon$ |
| 9 | Factor | $\rightarrow$ | $\underline{\text { number }}$ |
| 10 |  | $\mid$ | $\underline{\text { id }}$ |

Clearly,

$$
\operatorname{FIRST}^{+}(2), \operatorname{FIRST}^{+}(3), \& \operatorname{FIRST}^{+}(4)
$$

are disjoint, as are
FIRST+(6), FIRST ${ }^{+}$(7), \& FIRST ${ }^{+}$(8)
The grammar now has the $\operatorname{LL}(1)$ property

This transformation makes some grammars into LL(1) grammars.
There are languages for which no LL(1) grammar exists.

## First and Follow Sets

FIRst( $\alpha$ )
For some $\alpha \in(T \cup N T)^{*}$, define $\operatorname{FIRST}(\alpha)$ as the set of tokens that appear as the first symbol in some string that derives from $\alpha$
That is, $\underline{x} \in \operatorname{FIRST}(\alpha)$ iff $\alpha \Rightarrow^{*} \underline{x} \gamma$, for some $\gamma$
Follow(A)
For some $A \in N T$, define Follow $(A)$ as the set of symbols that can occur immediately after $A$ in a valid sentential form
FOLLOW(S) $=\{E O F\}$, where $S$ is the start symbol
To build Follow sets, we need FIRst sets ...

## Computing FIRST Sets

## Already studied in previous lectures

## Computing FOLLOW Sets

for each $A \in N T, \operatorname{FOLLOW}(A) \leftarrow \varnothing$
FOLLOW $(S) \leftarrow\{E O F\}$
while (FOLLOW sets are still changing)
for each $p \in P$, of the form $A \rightarrow B_{1} B_{2} \ldots B_{k}$
TRAILER $\leftarrow \operatorname{FOLLOW}(A)$
for $\mathrm{i} \leftarrow \mathrm{k}$ down to 1
if $B_{i} \in N T$ then // domain check
$\operatorname{FOLLOW}\left(B_{i}\right) \leftarrow \operatorname{FOLLOW}\left(B_{i}\right) \cup$ TRAILER
if $\varepsilon \in \operatorname{FIRST}\left(B_{i}\right) \quad / /$ add right context then TRAILER $\leftarrow$ TRAILER $\cup\left(\operatorname{FIRST}\left(B_{i}\right)-\{\varepsilon\}\right)$ else TRAILER $\leftarrow \operatorname{FIRST}\left(B_{i}\right) / /$ no $\varepsilon=>$ no right contex $\dagger$ else TRAILER $\leftarrow\left\{B_{i}\right\} \quad / / B_{i} \in T$ => only 1 symbol

## Classic Expression Grammar

| 0 | Goal |  | Expr | Symbol | FIRST | FOLLOW |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | Expr | $\rightarrow$ | Term Expr' | num | num | $\varnothing$ |
| 2 | Expr' | $\rightarrow$ | + Term Expr' | id | id | $\varnothing$ |
| 3 |  |  | - Term Expr' | + | + | $\varnothing$ |
| 4 |  |  | $\varepsilon$ | - | - | $\varnothing$ |
| 5 | Term | $\rightarrow$ | Factor Term' | * | * | $\varnothing$ |
| 6 | Term' | $\rightarrow$ | * Factor | ( | ( | $\varnothing$ |
| 7 |  |  | / Factor | ) | ) | $\varnothing$ |
| 8 |  |  | $\varepsilon$ | eof | eof | $\varnothing$ |
| 9 | Factor | $\rightarrow$ | number | $\varepsilon$ | $\varepsilon$ | $\varnothing$ |
| 10 |  |  | id | Goal | (id.num | eof |
| 11 |  |  | ( Expr) | Expr | (id.num | ). eof |
| $\operatorname{FIRST}^{+}(A \rightarrow \beta)$ is identical to |  |  |  | Exbr' | +. - | ). eof |
| FIRST( $\beta$ ) except for productiond 4 |  |  |  | Term | (id.num | +. -. ). eof |
| and 8 |  |  |  | Term' | *./. $\varepsilon$ | +.-. ). eof |
|  |  |  |  | Factor | (,id, num | +,-, *, /, ), eof |

## Classic Expression Grammar

| 0 | Goal |  | Expr |
| :---: | :---: | :---: | :---: |
| 1 | Expr | $\rightarrow$ | Term Expr' |
| 2 | Expr' | $\rightarrow$ | + Term Expr |
| 3 |  | \| | - Term Expr' |
| 4 |  | 1 | $\varepsilon$ |
| 5 | Term | $\rightarrow$ | Factor Term |
| 6 | Term' | $\rightarrow$ | * Factor |
| 7 |  | \| | / Factor |
| 8 |  | 1 | $\varepsilon$ |
| 9 | Factor |  | number |
| 10 |  |  | id |
| 11 |  |  | ( Expr ) |

| Prod'n | FIRST + |
| :---: | :---: |
| 0 | (.id.num |
| 1 | (.id.num |
| 2 | + |
| 3 | - |
| 4 | ع.). eof |
| 5 | (.id.num |
| 6 | $\star$ |
| 7 | $/$ |
| 8 | $\varepsilon .+.).$. eof |
| 9 | number |
| 10 | id |
| 11 | ( |

## Building Top-down Parsers for LL(1) Grammars

Given an LL(1) grammar, and its FIRST \& Follow sets ...

- Emit a routine for each non-terminal
- Nest of if-then-else statements to check alternate rhs's
- Each returns true on success and throws an error on false
- Simple, working (perhaps ugly) code
- This automatically constructs a recursive-descent parser

Improving matters

- Nest of if-then-else statements may be slow
- Good case statement implementation would be better
- What about a table to encode the options?
- Interpret the table with a skeleton, as we did in scanning

I don't know of a system that does this

## Building Top-down Parsers

## Strategy

- Encode knowledge in a table
- Use a standard "skeleton" parser to interpret the table

## Example

- The non-terminal Factor has 3 expansions
- (Expr) or Identifier or Number
- Table might look like: Terminal Symbols

## Building Top-down Parsers

Building the complete table

- Need a row for every NT \& a column for every T

LL(1) Expression Parsing Table

|  | + | - | $*$ | $/$ | Id | Num | $($ | $)$ | EOF |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Goal | - | - | - | - | 0 | 0 | 0 | - | - |
| Expr | - | - | - | - | 1 | 1 | 1 | - | - |
| Expr' | 2 | 3 | - | - | - | - | - | 4 | 4 |
| Term | - | - | - | - | 5 | 5 | 5 | - | - |
| Term' $^{\prime}$ | 8 | 8 | 6 | 7 | - | - | - | 8 | 8 |
| Fuilt |  |  |  |  |  |  |  |  |  |
| Factor | - | - | - | - | 10 | 9 | 11 | - | - |

## Building Top-down Parsers

Building the complete table

- Need a row for every NT \& a column for every T
- Need an interpreter for the table (skeleton parser)

## LL(1) Skeleton Parser

```
word \leftarrowNextWord() // Initial conditions, including
push EOF onto Stack // a stack to track local goals
push the start symbol, S, onto Stack
TOS }\leftarrow\mathrm{ top of Stack
loop forever
    if TOS = EOF and word = EOF then
        break & report success // exit on success
    else if TOS is a terminal then
        if TOS matches word then
            pop Stack // recognized TOS
            word }\leftarrow\mathrm{ NextWord()
        else report error looking for TOS // error exit
    else
                            // TOS is a non-terminal
        if TABLE[TOS,word] is A->\mp@subsup{B}{1}{}\mp@subsup{B}{2}{}\ldots..\mp@subsup{B}{k}{}}\mathrm{ then
            pop Stack // get rid of A
            push }\mp@subsup{B}{k}{},\mp@subsup{B}{k-1}{},\ldots,\mp@subsup{B}{1}{}\quad// in that order
        else break & report error expanding TOS
    TOS }\leftarrow\mathrm{ top of Stack
```

## Building Top-down Parsers

Building the complete table

- Need a row for every NT \& a column for every T
- Need a table-driven interpreter for the table
- Need an algorithm to build the table

Filling in TABLE $[X, y], X \in N T, y \in T$

1. entry is the rule $X \rightarrow \beta$, if $y \in \operatorname{FIRST}^{+}(X \rightarrow \beta)$

- entry is error if rule 1 does not define

If any entry has more than one rule, $G$ is not $\operatorname{LL}(1)$

We call this algorithm the $L L(1)$ table construction algorithm
